Spatial Transformation** 039 **Relative Speed Perception Network** [6] (RSPNet) 040 041

Rotation Net [17] (RotNet) applies geometrical transformation on the clips. The videos are rotated by various angles and the network predicts the class which it belongs to. Since the clips are rotated, it helps the network to not converge to a trivial solution.

047 Contrastive Video Representation Learning [27] 048 (CVRL) technique applies temporally coherent strong spatial augmentations to the input video. The contrastive 049 framework brings closer the clips from same video and 050 repels the clip from another video. With no labels attached. 051 the network learns to cluster the videos of same class but 052 053 with different visual content.

Video Clip Order Prediction [38] (VCOP) learns the representation by predicting the permutation order. The network is fed N clips from a video and then it predicts the

Temporal Discriminative Learning [36] (TDL) In contrast to CVRL, TDL works on temporal triplets. It looks into the temporal dimension of a video and targets them as unique instances. The anchor and positive belongs to same temporal interval and has a high degree of resemblance in

Playback Rate Prediction [7] (PRP) has two branch, generative and discriminative. Discriminative focuses on the classifying the clip's sampling rate, whereas, generative reconstructs the missing frame due to dilated sampling. Thus, the first one concentrates on temporal aspect and sec-

anplies contrastive loss in both spatial and temporal domain. Clips are samples from a same video to analyze the relative speed between them. A triplet loss pulls the clips with same speed together and pushes clips with different speed apart in the embedding space. To learn spatial features, InfoNCE loss [34] is applied. Clip from same video are positives whereas clips from different videos are negatives.

Video MAE [31] (V-MAE) applies a spatio-temporal tube masking to the input video. The pretext task is to reconstruct those missing tubes. Mean-squared error loss is applied between the masked tokens and the reconstructed tokens.

2.1. Architecture Details 110

111 Preliminary research has shown that 3D networks [33, 112 13] have outperformed 2D CNN variants on video recogni-113 tion tasks. We looked into three types of capacity - small, 114 medium and big on the basis of number of trainable param-115 eters. The architecture details of all networks are mentioned 116 in supplementary.

Small capacity networks: are resource efficient, imply-118 ing they can be trained in larger batches within short span 119 of time. The network selection is done on the basis of su-120 pervised training scores on Kinetics[18] and UCF101[19]. 121 ShuffleNet V1 2.0X [39] utilizes point-wise group convo-122 lutions and channel shuffling. SqueezeNet [15] reduces 123 the filter size and input channels to reduce the number of 124 parameters. MobileNet [28] has ResNet like architecture. 125 With its depthwise convolution, there's a reduction in model 126 size and the network can go more deep. 127

Medium capacity networks: Following the conventional 128 3D architectures for self-supervised learning approaches 129 C3D, R21D and R3D are used in this study. 130

Big Capacity networks: Comparing across four 131 transformer architectures, ViViT [2] Timesformer [4], 132 VideoSwin [24] and MViT [11], we selected VideoSwin, 133 because it outperforms others on Kinetics 400 dataset. 134

Based on [19], we probed into the performance com-135 parison of several versions of these architectures. We 136 choose 3D-ShuffleNet V1 2.0X, 3D-SqueezeNet, and 3D-137 MobileNet V2 1.0X networks based on their performance 138 on Kinetics and UCF-101 dataset 139

3D-ShuffleNet V1 2.0X [39]: It utilize point-wise group 140 convolutions and channel shuffling and has 3 different 141 stages. Within a stage, the number of output channel re-142 mains same. As we proceed to successive stage, the spa-143 tiotemporal dimension is reduced by a factor of 2 and the 144 number of channels are increased by a factor of 2. V1 de-145 notes version 1 of ShuffleNet and 2.0X denotes the 2 times 146 number of channels compared to original configuration. 147

3D-SqueezeNet [15]: It uses different alteration to reduce 148 the number of parameters as compared to the 2D version 149 which employs depthwise convolution. Those three modifi-150 151 cations are: 1) Change the shape of filters from 3x3 to 1x1, 2) Input channels to 3x3 filters is reduced, and, 3) to main-152 tain large activation maps high resolution is maintained till 153 deep layers. 154

155 **3D-MobileNet V2 1.0X [28]:** This network employs skip 156 connections like ResNet architecture in contrast to version 1. It helps the model in faster training and to build deeper 157 networks. There are also linear bottlenecks present in the 158 middle of layers. It helps in two ways as we reduce the 159 160 number of input channels: 1) With depthwise convolution, 161 the model size is reduced, and 2) at inference time, memory

usage is low. V2 denotes version 2 of mobilenet and 1.0X uses the original parameter settings.

The architectures of medium capacity networks are described as follows:

C3D [32]: This follows a simple architecture where two dimensional kernels have been extended to three dimensions. This was outlined to capture spatiotemporal features from videos. It has 8 convolutional layers, 5 pooling layers and 2 fully connected layers.

R3D [13]: The 2D CNN version of ResNet architecture is recasted into 3D CNNs. It has skip connections that helps make the gradient flow better as we build more deeper networks.

R(2+1)D [33]: In this architecture, 3D convolution is broken down into 2D and 1D convolution. 2D convolution is in spatial dimension and 1D convolution is along the temporal dimension. There are two benefits of this decomposition: 1) Increase in non-linearity as the number of layers have increased, and, 2) Due to factorization of 3D kernels, the optimization becomes easier.

VideoSwin [24] It is an inflated version of original Swin [23] transformer architecture. The attention is now spatiotemporal compared to previous which is only spatial. 3D tokens are constructed from the input using patch partition and sent to the network. The architecture includes four stages of transformer block and patch merging layers.

2.2. Original and Noise Datasets

We have shown the examples of each dataset used in the paper in Fig. 1.

The test datasets have different number of videos for different levels and types of noises. For Gaussian noise, we manipulated all 3783 samples. For noise level 1, apart from Gaussian, we had roughly 400 samples and all other levels of severity, we have approximately 550 samples. An example of each type of noise is shown in Fig. 2.

2.3. Pretext Tasks Configurations

Here, we briefly describe the configurations used in our training. For VCOP, RotNet and PRP, we just manipulated the type of augmentation from the original work. We applied Random Rotation, Resizing, Random Crop, Color Jittering and Random Horizontal Flipping to the input clip. CVRL has some extra data augmentation compare to the previous ones we mentioned. It includes grayscale and gamma adjustment as well. RSPNet also uses some temporal augmentation. For finetuning the augmentations are Resize and Center Crop for all the approaches.

The k-value for Momentum contrastive network is 16384 for RSPNet, it's 500 for TDL.

Figure 1: Example sample from each dataset.

Figure 2: **Example frame sample for each noise** Gaussian, Impulse, Shot and Speckle from left to right. Sample clips are provided in supplementary.

2.4. Datasets

Here we discuss datasets in detail. We use Kinetics-400 (K400) [18] and Something-Something V2 [12] for our pre-training. For the downstream task evaluation, we per-form our experiments on UCF-101 [29], HMDB-51 [21], and Diving48 [22]. Since, the pretraining and finetun-ing datasets are different, the performance variation will provide us a better picture about how much meaning-ful spatiotemporal features are learned by these networks. K400 has approximately 240k videos distributed evenly across 400 classes respectively. The approximate number of videos in finetuning datasets are: 1) UCF101-10k, 2) HMDB51-7k, and, 3)Diving48-16k. The datasets can be categorized into two ways:

Appearance-based: Kinetics, UCF101 and HMDB51 comes under this category [8, 14]. Kinetics videos length are generally 10s centered on human actions. It mainly constitutes singular person action, person-to-person actions and person-object action. For pre-training, we select a ran-dom subset of videos and maintain equal distribution from each class. Unless otherwise stated, pre-training is done on K400-50k subset for all experiments.

Temporal-based: In Kinetics, we can estimate the action
by looking at a single frame [8, 14]. From Fig. 1, top two
rows, we can see the person with a javelin and basketball.
This information helps in class prediction. Looking at bottom two rows (SSv2 and Diving48 respectively), we can't

describe the activity class until we look into few continuous frames. It shows that temporal aspect plays an important role for these datasets, that's why we categorize them into temporal-based datasets.

UCF-101 [29] : It's an action recognition dataset that spans over 101 classes. There are around 13,300 videos, with 100+ videos per class. The length of videos in this dataset varies from 4 to 10 seconds. It covers five types of categories: human-object interaction, human-human interaction, playing musical instruments, body motion and sports. **HMDB-51 [21] :** The number of videos in this dataset is 7000 comprising 51 classes. For each action, at least 70 videos are for training and 30 videos are for testing. The actions are clubbed into five categories: 1) General facial actions, 2) Facial actions with body movements, 3) General body movements, 4) Body movements with object interaction, and, 5) Body movements for human interaction.

3. Additional Results

Here, we will talk about some additional results, to further strengthen the claims made in the main paper.

3.1. Preliminary Experiments

Pretext tasks evaluation Figure 3 depicts the hidden representations of R21D network pretrained on different pretext tasks. Here the 50k subset of K-400 was used for pretraining, and finetuned on UCF-101.

ICCV 2023 Submission #6452. CONFIDENTIAL REVIEW COPY. DO NOT DISTRIBUTE.

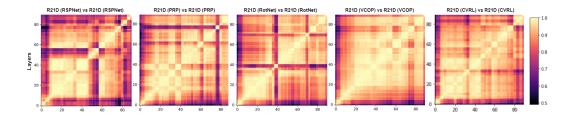

Figure 3: **Pretext tasks CKA maps** for RSPNet, PRP, RotNet, VCOP, CVRL on K-400 50k subset using R21D network (Left to right). R21D pretrained on K400 shows a semi-block structure for VCOP, indicating near-saturation condition of the network on this pretext task. It shows a more prominent grid-based structure on CVRL and RSPNet instead. These observations corroborate the quantitative results, where pretraining on K400 for both CVRL and RSPNet gives better performance.

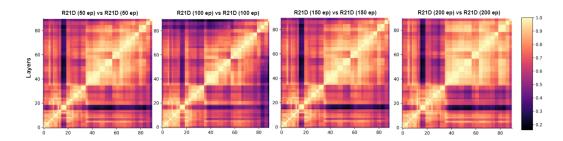

Figure 4: **Training time CKA maps** on 50, 100, 150, 200 epochs of R21D network on RSPNet pretext for K-400 10k subset (Left to right). The block structure is visible from 50 epochs itself, which then darkens and becomes prominent by 200 epochs. With 10k subset, the saturation starts hitting at 100 epochs.

	Non-	contrast	tive	(Contrasti	ive
Epochs	VCOP	Rot	PRP	CVRL	TDL	RSPNet
10k	18.9	15.0	9.2	22.2	9.9	30.2
30k	19.3	11.7	11.5	25.0	10.1	37.3
50k	17.3	12.2	10.2	29.3	9.5	40.2

Table 1: **Evaluation of different pretext tasks** on different subset size on R21D network on HMDB51 dataset.

Linear Probing vs Finetuning Firstly, we discuss linear probing (LP) vs finetuning (FT) results for different pretext tasks and different architectures. From Table 2, we can see that FT outperforms LP by a margin of approximately 20% and 40% on ShuffleNet and R21D respectively. Thus, we perform finetuning for all of our analysis.

373 Network Parameters We have shown the performance
across different architectures in Table 3. ShuffleNet and
R21D performs the best across small and medium capacity networks in most of the pretext tasks. Thus, we choose
ShuffleNet and R21D for our benchmark analysis.

Network	LP	FT	RotNet	VCOP	PRP
Shuffle	\checkmark		4.3	12.3	2.8
Shume		\checkmark	16.6	40.8	21.9
R21D	\checkmark		2.7	12.2	4.6
K21D		\checkmark	41.2	51.5	46.2

Table 2: Downstream accuracy classification on UCF-101dataset. FT: Finetuning LP: Linear Probing

3.2. Effect of dataset size

In Table 1, we extend results for different pretext tasks on HMDB51 dataset. Similar to UCF101, *the scale in subset size doesn't reciprocate to gain in performance* for all pretext tasks on HMDB51 dataset. From Figures 5 and 6, we see that performance increase for Swin by a good margin, whereas in case of ShuffleNet and R21D it's relatively less beyond 50k subset.

Training time Table 4 shows VideoSwin saturates at 150 epochs on UCF101 whereas CNN architectures saturates earlier (100 epochs) which reflects limitation of model capacity. Figure 4 shows the emergence of block structures for R21D network trained on RSPNet for K400 10k. The saturation point has reached earlier around 100 epochs which

Networks	Parameters	GFLOPs	$\operatorname{Rot}^{\dagger}$	VCOP †	$\mathbf{P}\mathbf{R}\mathbf{P}^{\dagger}$	RSPNet
ShuffleNet	4.6M	1.1	42.2	41.6	41.1	68.8
MobileNet	3.1M	1.1	38.0	40.0	37.4	63.1
SqueezeNet	1.9M	1.8	41.3	41.4	39.2	62.9
C3D	27.7M	77.2	57.7	54.5	58.1	67.6
R3D	14.4M	39.8	51.1	50.7	52.1	62.1
R(2+1)D	14.4M	42.9	46.9	56.8	58.9	78.0

Table 3: Comparison of FLOPs and trainable parameters for each network on UCF101 dataset. † - pretraining on Kinetics 700 [5].

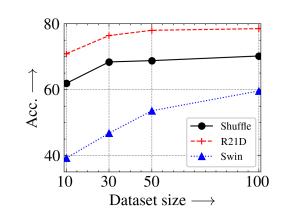

Figure 5: Multiple architectures and data subsets on UCF101. Pretext task is RSPNet. (x-axis: subset size, y-axis: Top-1 Accuracy) Here, 10 means 10k dataset subset, 30 means 30k and so on.

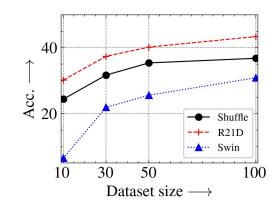

Figure 6: Multiple architectures and data subsets on HMDB51. Pretext task is RSPNet. (x-axis: subset size, y-axis: Top-1 Accuracy) Here, 10 means 10k dataset subset, 30 means 30k and so on.

supports the hypothesis in main work that CNN architectures mostly saturates around 100 epochs. We see similar
pattern even after increasing the dataset size.

3.3. Impact of task complexity

Figures 7 shows for ShuffleNet dark patterns with increase in complexity. R21D shows staggering grids. It supports our hypothesis that *model capacity* plays an important role to learn meaningful features and always increasing the complexity doesn't reciprocate to *better spatio-temporal features*.

3.4. Effect of data distrbituion

Figure 9 illustrates CKA maps for networks pretrained on *different source datasets* - for R21D pretrained on K400-50k on VCOP and CVRL respectively. The stark difference in semi-block structure of *spatial (VCOP)* vs grid-like structure of *spatio-temporal (CVRL)* shows spatio-temporal outperforms spatial pretext task.

3.5. Robustness of SSL tasks

Table 5 shows performance of each pretext on each type of noise for severity level 1. Fig. 8 shows a relative decrease in performance for three different severity level on UCF101 dataset. *Non-contrastive* tasks are more robust than *contrastive* on average even at different severity levels.

3.6. Feature Analysis

We employ knowledge distillation to evaluate how complementary information from different datasets can be used to train a student model that could take advantage of this in terms of performance gain and training time reduction. Here we show the numbers quantitatively. Table 6 shows smaller architecture leans complementary information whereas bigger architecture depends on pretext task. Table 7 shows that for each pretext task, we learn *complimentary information* from two *different source* datasets. Thus, student always outperforms the teachers. Table 8 shows that distilling knowledge from a *spatial* and a *temporal* task outperforms the standalone *spatio-temporal* task in both *contrastive* and *non-contrastive* case.

ICCV 2023 Submission #6452. CONFIDENTIAL REVIEW COPY. DO NOT DISTRIBUTE.

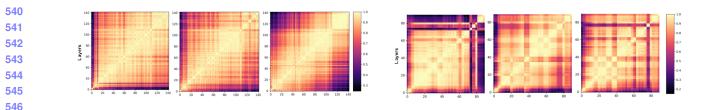

Figure 7: **Complexity CKA maps** PRP ShuffleNet (Left) and R21D (Right) network increasing complexity from 2 to 4 (Left to right). ShuffleNet has lower performance than R21D, and it shows darkest patterns when complexity is increased from 3 to 4. For both of these complexities, R21D shows staggering grids.

Epochs		Shu	ıffle			R2	1D			Sv	vin	
	10k	30k	50k	100k	10k	30k	50k	100k	10k	30k	50k	100k
50	59.1	66.3	68.1	68.9	66.8	71.1	75.0	77.2	-	40.4	44.9	52.0

Table 9: Top K Clip Retrieval on HMDB51/UCF101 across different architectures for RSPNet.

692 depth, the works outperforming us are AVTS[20], GDT [26] 693 in multi-modal and VIMPAC [30], VideoMAE [31], TCLR 694 [9] and CVRL [27] in single modality. AVTS and GDT uses 695 two modalities, have more number of frames and AVTS 696 also uses a bigger spatial size. Coming to Generative-based, both VIMPAC and VideoMAE uses a bigger backbone ar-697 chitecture. CVRL uses a longer temporal sequence and big-698 ger frame resolution compared to ours and TCLR utilize 64 699 700 effective frames. Thus, the performance on HMDB51 is 701 still competitive.
